Example: multidimensional scaling

Suppose, we have a pairwise distance matrix for N d-dimensional objects $D \in \mathbb{R}^{N \times N}$. Given this matrix, our goal is to recover the initial coordinates $W_i \in \mathbb{R}^d$, i = 1, ..., N.

Example: multidimensional scaling

Suppose, we have a pairwise distance matrix for N d-dimensional objects $D \in \mathbb{R}^{N \times N}$. Given this matrix, our goal is to recover the initial coordinates $W_i \in \mathbb{R}^d$, $i = 1, \ldots, N$.

$$L(W) = \sum_{i,j=1}^{N} (\|W_i - W_j\|_2^2 - D_{i,j})^2 \to \min_{W \in \mathbb{R}^{N \times d}}$$

Example: multidimensional scaling

Suppose, we have a pairwise distance matrix for N d-dimensional objects $D \in \mathbb{R}^{N \times N}$. Given this matrix, our goal is to recover the initial coordinates $W_i \in \mathbb{R}^d$, $i = 1, \ldots, N$.

$$L(W) = \sum_{i,j=1}^{N} (\|W_i - W_j\|_2^2 - D_{i,j})^2 \to \min_{W \in \mathbb{R}^{N \times d}}$$

Link to a nice visualization 🗘, where one can see, that gradient-free methods handle this problem much slower, especially in higher dimensions.

Question

Is it somehow connected with PCA?

Suppose we need to solve the following problem:

$$L(w) \to \min_{w \in \mathbb{R}^d}$$

Suppose we need to solve the following problem:

$$L(w) \to \min_{w \in \mathbb{R}^d}$$

with the Gradient Descent (GD) algorithm:

$$w_{k+1} = w_k - \alpha_k \nabla_w L(w_k)$$

Suppose we need to solve the following problem:

$$L(w) \to \min_{w \in \mathbb{R}^d}$$

with the Gradient Descent (GD) algorithm:

$$w_{k+1} = w_k - \alpha_k \nabla_w L(w_k)$$

Is it possible to replace $\nabla_w L(w_k)$ using only zero-order information?

େ ଚେ 🗢

Suppose we need to solve the following problem:

$$L(w) \to \min_{w \in \mathbb{R}^d}$$

with the Gradient Descent (GD) algorithm:

$$w_{k+1} = w_k - \alpha_k \nabla_w L(w_k)$$

Is it possible to replace $\nabla_w L(w_k)$ using only zero-order information?

intormation

Yes, but at a cost.

Suppose we need to solve the following problem:

$$L(w) \to \min_{w \in \mathbb{R}^d}$$

with the Gradient Descent (GD) algorithm:

$$w_{k+1} = w_k - \alpha_k \nabla_w L(w_k)$$

Is it possible to replace $\nabla_w L(w_k)$ using only zero-order information?

Yes, but at a cost.

One can consider 2-point gradient estimator a G:

$$G = d\frac{L(w + \varepsilon v) - L(w - \varepsilon v)}{2\varepsilon}v,$$

where v is spherically symmetric.

^al suggest a nice presentation about gradient-free methods

Backward (reverse) mode automatic differentiation

i Question

Note, that for the same price of computations as it was in the forward mode we have the full vector of gradient $\nabla_w L$. Is it a free lunch? What is the cost of acceleration?

Backward (reverse) mode automatic differentiation

i Question

Note, that for the same price of computations as it was in the forward mode we have the full vector of gradient $\nabla_w L$. Is it a free lunch? What is the cost of acceleration?

Answer Note, that for using the reverse mode AD you need to store all intermediate computations from the forward pass. This problem could be somehow mitigated with the gradient checkpointing approach, which involves necessary recomputations of some intermediate values. This could significantly reduce the memory footprint of the large machine-learning model.

For i = N, ..., 1:

Reverse mode automatic differentiation algorithm Suppose, we have a computational graph $v_i, i \in [1; N]$.

Our goal is to calculate the derivative of the output of this graph with respect to all inputs variable w,

i.e. $\nabla_w v_N = \left(\frac{\partial v_N}{\partial w_1}, \dots, \frac{\partial v_N}{\partial w_d}\right)^T$. This idea implies propagation of the gradient of the function with respect to the intermediate variables from the end to the origin, that is why we can introduce the notation:

$$\overline{v_i} = \frac{\partial L}{\partial v_i} = \frac{\partial v_N}{\partial v_i}$$

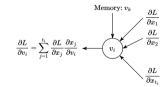

Figure 24: Illustration of reverse chain rule to calculate the derivative of the function L with respect to the node v_i .

FORWARD PASS

For i = 1, ..., N:

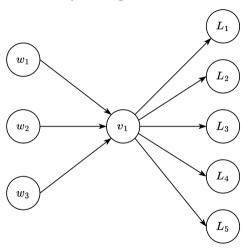

• Compute and store the values of v_i as a function of its parents (inputs)

BACKWARD PASS

For i = N, ..., 1:

• Compute the derivative $\overline{v_i}$ using the backward chain rule and information from all of its children (outputs) (x_1,\ldots,x_{t_i}) :

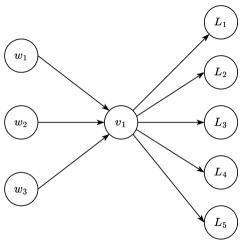

$$\overline{v_i} = \frac{\partial L}{\partial v_i} = \sum_{j=1}^{t_i} \frac{\partial L}{\partial x_j} \frac{\partial x_j}{\partial v_i}$$

$$i$$
 Question

Which of the AD modes would you choose (forward/ reverse) for the following computational graph of primitive arithmetic operations? Suppose, you are needed to compute the jacobian $J = \left\{ \frac{\partial L_i}{\partial w_i} \right\}$

Figure 25: Which mode would you choose for calculating gradients there?

i Question

Which of the AD modes would you choose (forward/ reverse) for the following computational graph of primitive arithmetic operations? Suppose, you are needed to compute the jacobian $J = \left\{ \frac{\partial L_i}{\partial w_j} \right\}_{i,j}$

Answer Note, that the reverse mode computational time is proportional to the number of outputs here, while the forward mode works proportionally to the number of inputs there. This is why it would be a good idea to consider the forward mode AD.

Figure 25: Which mode would you choose for calculating gradients there?

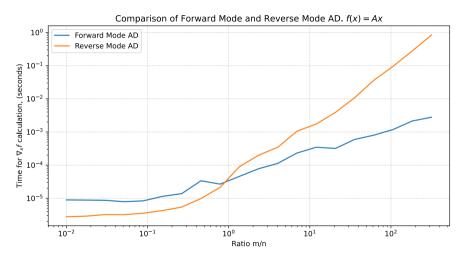

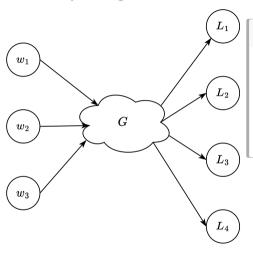

Figure 26: \clubsuit This graph nicely illustrates the idea of choice between the modes. The n=100 dimension is fixed and the graph presents the time needed for Jacobian calculation w.r.t. x for f(x)=Ax

 $\stackrel{\longrightarrow}{=} f \to \min_{x,y,z}$ Automatic differentiation

i Question

Which of the AD modes would you choose (forward/ reverse) for the following computational graph of primitive arithmetic operations? Suppose, you are needed to compute the jacobian $J = \left\{\frac{\partial L_i}{\partial w_j}\right\}_{i,j}.$ Note, that G is an arbitrary computational graph

Figure 27: Which mode would you choose for calculating gradients there?

i Question

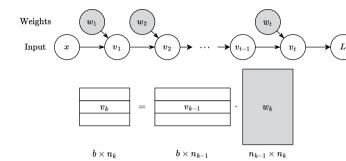

Which of the AD modes would you choose (forward/ reverse) for the following computational graph of primitive arithmetic operations? Suppose, you are needed to compute the jacobian $J = \left\{\frac{\partial L_i}{\partial w_j}\right\}_{i,j}.$ Note, that G is an arbitrary computational graph

Answer It is generally impossible to say it without some knowledge about the specific structure of the graph G. Note, that there are also plenty of advanced approaches to mix forward and reverse mode AD, based on the specific G structure.

Figure 27: Which mode would you choose for calculating gradients there?

the parametrization:

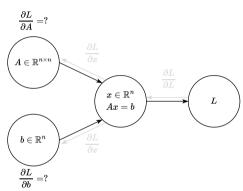

Figure 29: \boldsymbol{x} could be found as a solution of linear system

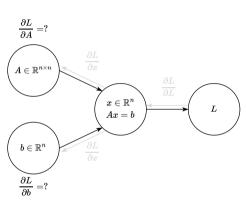

Suppose, we have an invertible matrix A and a vector b, the vector x is the solution of the linear system Ax=b, namely one can write down an analytical solution $x=A^{-1}b$, in this example we will show, that computing all derivatives $\frac{\partial L}{\partial A}, \frac{\partial L}{\partial b}, \frac{\partial L}{\partial x}$, i.e. the backward pass, costs approximately the same as the forward pass. It is known, that the differential of the function does not depend on the parametrization:

$$dL = \left\langle \frac{\partial L}{\partial x}, dx \right\rangle = \left\langle \frac{\partial L}{\partial A}, dA \right\rangle + \left\langle \frac{\partial L}{\partial b}, db \right\rangle$$

Given the linear system, we have:

$$Ax = b$$

$$dAx + Adx = db \rightarrow dx = A^{-1}(db - dAx)$$

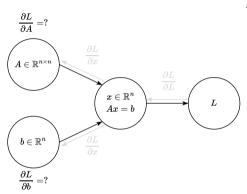

The straightforward substitution gives us:

$$\left\langle \frac{\partial L}{\partial x}, A^{-1}(db - dAx) \right\rangle = \left\langle \frac{\partial L}{\partial A}, dA \right\rangle + \left\langle \frac{\partial L}{\partial b}, db \right\rangle$$

Figure 30: \boldsymbol{x} could be found as a solution of linear system

⊕ ∩ €

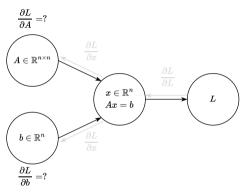

The straightforward substitution gives us:

$$\left\langle \frac{\partial L}{\partial x}, A^{-1}(db - dAx) \right\rangle = \left\langle \frac{\partial L}{\partial A}, dA \right\rangle + \left\langle \frac{\partial L}{\partial b}, db \right\rangle$$

$$\left\langle -A^{-T}\frac{\partial L}{\partial x}x^{T}, dA\right\rangle + \left\langle A^{-T}\frac{\partial L}{\partial x}, db\right\rangle = \left\langle \frac{\partial L}{\partial A}, dA\right\rangle + \left\langle \frac{\partial L}{\partial b}, db\right\rangle$$

Figure 30: x could be found as a solution of linear system

The straightforward substitution gives us:

$$\left\langle \frac{\partial L}{\partial x}, A^{-1}(db - dAx) \right\rangle = \left\langle \frac{\partial L}{\partial A}, dA \right\rangle + \left\langle \frac{\partial L}{\partial b}, db \right\rangle$$

$$\left\langle -A^{-T}\frac{\partial L}{\partial x}x^T,dA\right\rangle + \left\langle A^{-T}\frac{\partial L}{\partial x},db\right\rangle = \left\langle \frac{\partial L}{\partial A},dA\right\rangle + \left\langle \frac{\partial L}{\partial b},db\right\rangle$$
 Therefore:

$$\frac{\partial L}{\partial A} = -A^{-T} \frac{\partial L}{\partial x} x^{T} \quad \frac{\partial L}{\partial b} = A^{-T} \frac{\partial L}{\partial x}$$

Figure 30: x could be found as a solution of linear system

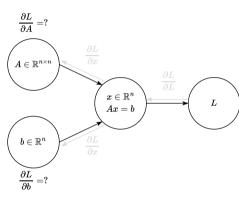

Figure 30: \boldsymbol{x} could be found as a solution of linear system

The straightforward substitution gives us:

the backward pass even cheaper.

$$\left\langle \frac{\partial L}{\partial x}, A^{-1}(db - dAx) \right\rangle = \left\langle \frac{\partial L}{\partial A}, dA \right\rangle + \left\langle \frac{\partial L}{\partial b}, db \right\rangle$$

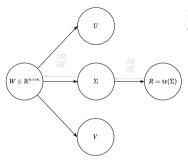

$$\left\langle -A^{-T}\frac{\partial L}{\partial x}x^T, dA \right\rangle + \left\langle A^{-T}\frac{\partial L}{\partial x}, db \right\rangle = \left\langle \frac{\partial L}{\partial A}, dA \right\rangle + \left\langle \frac{\partial L}{\partial b}, db \right\rangle$$

Therefore

$$\frac{\partial L}{\partial A} = -A^{-T} \frac{\partial L}{\partial x} x^{T} \quad \frac{\partial L}{\partial b} = A^{-T} \frac{\partial L}{\partial x}$$

It is interesting, that the most computationally intensive part here is the matrix inverse, which is the same as for the forward pass. Sometimes it is even possible to store the result itself, which makes

 $f \to \min_{x,y,z}$ Automatic differentiation

Suppose, we have the rectangular matrix $W \in \mathbb{R}^{m \times n}$, which has a singular value decomposition:

$$W = U\Sigma V^T, \quad U^T U = I, \quad V^T V = I, \quad \Sigma = \mathsf{diag}(\sigma_1, \dots, \sigma_{\min(m,n)})$$

1. Similarly to the previous example:

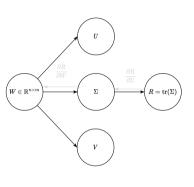

$$W = U\Sigma V^{T}$$

$$dW = dU\Sigma V^{T} + Ud\Sigma V^{T} + U\Sigma dV^{T}$$

$$U^{T}dWV = U^{T}dU\Sigma V^{T}V + U^{T}Ud\Sigma V^{T}V + U^{T}U\Sigma dV^{T}V$$

$$U^{T}dWV = U^{T}dU\Sigma + d\Sigma + \Sigma dV^{T}V$$

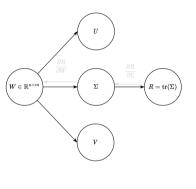

2. Note, that $U^TU=I \to dU^TU+U^TdU=0$. But also $dU^TU=(U^TdU)^T$, which actually involves, that the matrix U^TdU is antisymmetric:

$$(\boldsymbol{U}^T d\boldsymbol{U})^T + \boldsymbol{U}^T d\boldsymbol{U} = 0 \quad \to \quad \operatorname{diag}(\boldsymbol{U}^T d\boldsymbol{U}) = (0, \dots, 0)$$

The same logic could be applied to the matrix \boldsymbol{V} and

$$\mathsf{diag}(dV^TV) = (0,\dots,0)$$

2. Note, that $U^TU=I \to dU^TU+U^TdU=0$. But also $dU^TU=(U^TdU)^T$, which actually involves, that the matrix U^TdU is antisymmetric:

$$(\boldsymbol{U}^T d\boldsymbol{U})^T + \boldsymbol{U}^T d\boldsymbol{U} = 0 \quad \to \quad \operatorname{diag}(\boldsymbol{U}^T d\boldsymbol{U}) = (0, \dots, 0)$$

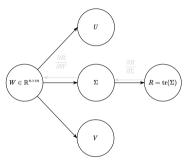

The same logic could be applied to the matrix \boldsymbol{V} and

$$\mathsf{diag}(dV^TV) = (0, \dots, 0)$$

3. At the same time, the matrix $d\Sigma$ is diagonal, which means (look at the 1.) that

$$\mathsf{diag}(U^T dW V) = d\Sigma$$

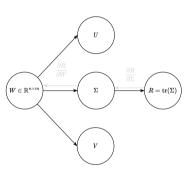

Here on both sides, we have diagonal matrices.

4. Now, we can decompose the differential of the loss function as a function of Σ - such problems arise in ML problems, where we need to restrict the matrix rank:

$$\begin{split} dL &= \left\langle \frac{\partial L}{\partial \Sigma}, d\Sigma \right\rangle \\ &= \left\langle \frac{\partial L}{\partial \Sigma}, \mathsf{diag}(\boldsymbol{U}^T dW \boldsymbol{V}) \right\rangle \\ &= \mathsf{tr}\left(\frac{\partial L}{\partial \Sigma}^T \mathsf{diag}(\boldsymbol{U}^T dW \boldsymbol{V})\right) \end{split}$$

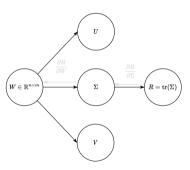

5. As soon as we have diagonal matrices inside the product, the trace of the diagonal part of the matrix will be equal to the trace of the whole matrix:

$$\begin{split} dL &= \operatorname{tr} \left(\frac{\partial L}{\partial \Sigma}^T \operatorname{diag}(U^T dW V) \right) \\ &= \operatorname{tr} \left(\frac{\partial L}{\partial \Sigma}^T U^T dW V \right) \\ &= \left\langle \frac{\partial L}{\partial \Sigma}, U^T dW V \right\rangle \\ &= \left\langle U \frac{\partial L}{\partial \Sigma} V^T, dW \right\rangle \end{split}$$

6. Finally, using another parametrization of the differential

$$\left\langle U \frac{\partial L}{\partial \Sigma} V^T, dW \right\rangle = \left\langle \frac{\partial L}{\partial W}, dW \right\rangle$$

$$\frac{\partial L}{\partial W} = U \frac{\partial L}{\partial \Sigma} V^T,$$

This nice result allows us to connect the gradients $\frac{\partial L}{\partial W}$ and $\frac{\partial L}{\partial \Sigma}.$

Hessian vector product without the Hessian

When you need some information about the curvature of the function you usually need to work with the hessian. However, when the dimension of the problem is large it is challenging. For a scalar-valued function $f: \mathbb{R}^n \to \mathbb{R}$, the

Hessian at a point $x \in \mathbb{R}^n$ is written as $\nabla^2 f(x)$. A Hessian-vector product function is then able to evaluate

$$v \mapsto \nabla^2 f(x) \cdot v$$

for any vector $v \in \mathbb{R}^n$. We have to use the identity

$$\nabla^2 f(x)v = \nabla[x \mapsto \nabla f(x) \cdot v] = \nabla g(x),$$

where $g(x) = \nabla f(x)^T \cdot v$ is a new vector-valued function that dots the gradient of f at x with the vector v.

import jax.numpy as jnp

def hvp(f, x, v): return grad(lambda x: inp.vdot(grad(f)(x), v))(x)

Hutchinson Trace Estimation ²

This example illustrates the estimation the Hessian trace of a neural network using Hutchinson's method, which is an algorithm to obtain such an estimate from matrix-vector products:

Let $X \in \mathbb{R}^{d \times d}$ and $v \in \mathbb{R}^d$ be a random vector such that $\mathbb{E}[vv^T] = I$. Then,

$$\operatorname{Tr}(X) = \mathbb{E}[v^T X v] = \frac{1}{V} \sum_{i=1}^{V} v_i^T X v_i$$
